UP-VLA: A Unified Understanding and Prediction Model for Embodied Agent

Anonymous Authors [1]

Abstract

Vision-Language-Action (VLA) models show promise for robotic control by leveraging semantic understanding from large-scale vision-language pretraining. However, existing VLAs struggle with precise spatial reasoning and low-level dynamics understanding crucial for fine-grained manipulation tasks. We introduce UP-VLA, a unified framework that jointly trains on multi-modal understanding and future visual prediction to capture both high-level semantic information and spatial dynamics awareness. UP-VLA employs a shared autoregressive backbone (Phi-1.5) with dual visual streams: CLIP-ViT for semantic understanding and VQ-GAN for discrete visual prediction. Through task-aware prompting and attention mechanisms, our unified model handles understanding, prediction, and action generation seamlessly. We demonstrate state-of-the-art performance on CALVIN long-horizon benchmarks, achieving 4.08 average task completion length on ABC→D (vs. 3.06 for GR-1) and 0.699 success rate on 5-task sequences (vs. 0.401 for GR-1). In real-world manipulation, UP-VLA achieves 80% success on seen tasks and 58% on challenging unseen object scenarios. Ablation studies confirm the complementary benefits of multi-modal understanding and visual prediction pretraining for embodied intelligence.

1. Introduction

Recent advances in Vision-Language Models (VLMs) have opened new possibilities for embodied AI by enabling robots to understand complex instructions and reason about visual scenes (Brohan et al., 2022; Ma et al., 2023). Vision-Language-Action (VLA) models extend this paradigm by directly predicting robot actions from visual observations and natural language commands, showing promising results in manipulation tasks (Stone et al., 2023).

However, current VLA models face a fundamental limitation: they inherit strong semantic capabilities from vision-language pretraining but often lack the spatial precision and dynamics awareness necessary for fine-grained robotic control. Most existing approaches focus exclusively on high-level understanding tasks like Visual Question Answering (VQA), overlooking the importance of predictive modeling that captures temporal dynamics and spatial relationships crucial for manipulation.

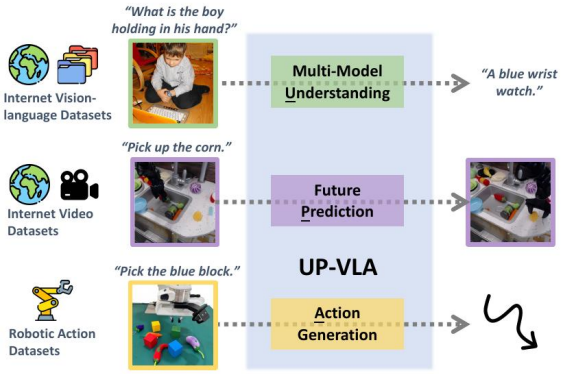

Figure 1. UP-VLA integrates multi-modal understanding, future prediction, and action generation in a unified framework. By jointly training on vision-language datasets, internet video, and robotic action data, UP-VLA captures both semantic understanding and spatial dynamics for improved embodied intelligence.

This limitation manifests in several ways. First, VLAs trained primarily on static vision-language data struggle with tasks requiring precise spatial reasoning, such as object insertion or delicate assembly operations. Second, they often fail to generalize to scenarios involving novel objects or environments that differ from their training distribution, as they lack robust world models for understanding how scenes evolve over time.

To address these challenges, we propose UP-VLA (Unified Understanding and Prediction VLA), a novel framework that jointly optimizes multi-modal understanding and future visual prediction within a single autoregressive model (Figure 1). Our key insight is that combining semantic grounding with temporal prediction can endow VLAs with both high-level reasoning capabilities and low-level spatial dynamics awareness.

UP-VLA builds upon a unified autoregressive backbone based on Phi-1.5 (Li et al., 2023), incorporating two distinct visual processing streams: (1) a continuous CLIP-ViT en-

coder for multi-modal understanding (MMU) that handles vision-language tasks, and (2) a discrete VQ-GAN tokenizer for future visual prediction (PRE) that captures spatial and temporal dynamics. Through a novel task-aware prompting and attention mechanism, our model seamlessly switches between understanding, prediction, and action generation modes while maintaining parameter sharing across all tasks.

Our training strategy proceeds in two stages: (1) co-pretraining the MMU stream on LLaVA-665k vision-language pairs while training the PRE stream on Bridge robotics demonstrations, and (2) joint finetuning on downstream robot data while continuing MMU training to prevent catastrophic forgetting.

We evaluate UP-VLA on the challenging CALVIN benchmark for long-horizon manipulation tasks (Mees et al., 2022) and demonstrate significant improvements over state-of-the-art baselines. On the ABC→D zero-shot generalization task, UP-VLA achieves an average completion length of 4.08 compared to 3.06 for GR-1, representing a 33% improvement. For the more challenging 5-task sequence completion, our model achieves a 0.699 success rate compared to 0.401 for GR-1. In real-world experiments with a Panda robot arm, UP-VLA demonstrates robust performance with 80% success on seen tasks and 58% success on challenging unseen object scenarios.

Contributions: (1) We introduce a unified VLA training paradigm that jointly optimizes multi-modal understanding and future visual prediction to capture both semantic and spatial dynamics information. (2) We design a task-aware prompting and attention mechanism enabling a single autoregressive model to handle understanding, prediction, and action generation. (3) We achieve state-of-the-art performance on CALVIN benchmarks and demonstrate improved real-world manipulation capabilities, especially on precise and unseen-object tasks. (4) We provide comprehensive ablation studies demonstrating the complementary benefits of multi-modal understanding and predictive pretraining.

2. Related Work

Vision-Language-Action Models. Early work in language-conditioned robotics focused on grounding natural language instructions to specific actions or waypoints (Mei et al., 2016; Misra et al., 2017). Recent advances have leveraged large-scale pretraining to develop more general VLA models. RT-1 (Brohan et al., 2022) and RT-2 (Brohan et al., 2023) demonstrate how robotics transformers can learn from diverse manipulation data, while maintaining semantic understanding through vision-language pretraining. PaLM-E integrates large language models with visual encoders for embodied reasoning (Driess et al., 2023). However, these approaches primarily focus on scaling data and model size, without explicitly addressing the spatial precision challenges inherent in manipulation tasks.

Predictive Models for Robotics. Video prediction and world modeling have shown promise for robotic control by learning temporal dynamics from visual data (**?**). Recent work has explored autoregressive video prediction for action synthesis (**?**). GR-1 (**?**) demonstrates that future frame prediction can improve robotic manipulation performance, particularly for tasks requiring precise spatial understanding. UniPi (**?**) and Susie (Black et al., 2023) further explore prediction-based approaches for embodied AI. Our work builds upon these insights but uniquely combines predictive modeling with multi-modal understanding in a unified framework.

Multi-Modal Understanding. Vision-language models like CLIP (Radford et al., 2021) and LLaVA (**?**) have revolutionized visual understanding by learning rich representations from large-scale image-text datasets. In robotics, several works have explored incorporating VLM capabilities into action models (Ma et al., 2023; Stone et al., 2023). CLIPort (Shridhar et al., 2022) uses CLIP features for spatial understanding in manipulation. However, most existing approaches use frozen VLM features or fine-tune only small portions of the model, limiting their ability to adapt to robotic scenarios.

Unified Architectures. Recent work has explored unified architectures that can handle multiple tasks within a single model. Show-o (Xie et al., 2024) demonstrates unified understanding and generation for vision-language tasks. In robotics, some works have attempted to unify different modalities (Reuss et al., 2024), but none have successfully combined semantic understanding with predictive modeling for embodied AI.

Our work differs from existing approaches in three key ways: (1) we jointly optimize understanding and prediction objectives rather than treating them separately, (2) we use task-aware attention to enable seamless switching between different modes within a single model, and (3) we demonstrate that this unified approach leads to significant improvements in both semantic understanding and spatial precision for robotic manipulation.

3. Preliminaries

Vision-Language-Action Formulation. We consider the standard VLA setup where an agent receives visual observations $o_t \in \mathbb{R}^{H\times W\times 3}$ and natural language instructions τ to predict actions $a_t \in \mathbb{R}^d$. The goal is to learn a policy $\pi : (o_t, \tau) \to a_t$ that can generalize to novel instructions and environments.

Autoregressive Modeling. Following recent trends in gen-

erative modeling, we frame both understanding and action prediction as autoregressive sequence generation. For a sequence $x = \{x_1, \ldots, x_T\}$, the model learns to predict the next token x_{t+1} given the history $x_{1:t}$:

$$p(x) = \prod_{t=1}^{T} p(x_t | x_{1:t-1}) \tag{1}$$

Multi-Modal Tokenization. To enable unified processing, we tokenize different modalities into discrete tokens. Visual observations are processed through either continuous encoders (CLIP-ViT) for understanding or discrete tokenizers (VQ-GAN) for prediction. Language instructions are tokenized using standard subword tokenization, and actions are discretized into bins following RT-1 (Brohan et al., 2022).

Task-Aware Processing. Our model handles three distinct objectives: (1) Multi-modal Understanding (MMU): answering questions about visual scenes, (2) Visual Prediction (PRE): generating future frames given current observations, and (3) Action Generation (ACT): predicting robot actions from observations and instructions. The key challenge is enabling seamless switching between these modes while maintaining parameter sharing.

4. Methodology

UP-VLA employs a unified autoregressive architecture that seamlessly handles multi-modal understanding, future visual prediction, and action generation through task-aware prompting and attention mechanisms. Figure 2 shows our two-stage training approach.

4.1. Architecture Design

Unified Backbone. Our model builds upon Phi-1.5 as the core autoregressive transformer, chosen for its strong reasoning capabilities and efficient parameter usage. The unified backbone enables parameter sharing across all tasks while maintaining task-specific processing through attention masking.

Dual Visual Streams. UP-VLA incorporates two complementary visual processing pathways:

Multi-Modal Understanding (MMU) Stream: Uses a continuous CLIP-ViT encoder to extract high-level semantic features from visual observations. This stream specializes in understanding scene content, object relationships, and responding to visual questions.

Predictive (PRE) Stream: Employs a VQ-GAN tokenizer to convert visual observations into discrete tokens, enabling autoregressive prediction of future frames. This stream captures low-level spatial details and temporal dynamics crucial for precise manipulation.

The dual-stream design allows our model to leverage both semantic understanding and spatial precision, addressing the key limitation of existing VLA approaches.

4.2. Task-Aware Prompting and Attention

To enable seamless task switching within a single model, we design a novel prompting and attention scheme (Figure 3). The key innovations are:

Task-Dependent Token Ordering. For MMU tasks, continuous image tokens are placed before language tokens, following the standard vision-language model convention. For PRE tasks, discrete image tokens are placed after language instructions, enabling autoregressive generation conditioned on textual context.

Special Control Tokens. We introduce a special `[PRE]` token that triggers prediction mode. When this token appears in the sequence, the model switches to generating discrete visual tokens using the VQ-GAN vocabulary. Similarly, action generation is triggered by task-specific prompts.

Attention Masking. We implement task-aware attention masks that prevent information leakage between different objectives during training. For MMU tasks, the model attends to both image and language tokens bidirectionally. For PRE tasks, autoregressive masking ensures proper temporal ordering of predicted frames.

The attention mechanism employs a dynamic mask matrix $M \in \{0, 1\}^{L \times L}$ where L is sequence length. For position i attending to position j, $M_{ij} = 1$ if attention is allowed, 0 otherwise. During MMU tasks, we use bidirectional masking: $M_{ij} = 1$ for all valid token pairs. For PRE tasks, we enforce causal masking: $M_{ij} = 1$ iff $j \leq i$, ensuring the model cannot access future visual information during autoregressive prediction.

4.3. Training Strategy

Our training proceeds in two carefully designed stages to balance multi-modal understanding with robotic capabilities:

Stage 1: Co-Pretraining. We simultaneously train the MMU stream on LLaVA-665k vision-language pairs and the PRE stream on Bridge robotics demonstrations (25k episodes). This stage establishes strong foundations for both semantic understanding and dynamics modeling.

The MMU objective minimizes cross-entropy loss for question answering:

$$\mathcal{L}_{MMU} = -\sum_{t} \log p(y_t | x_{1:t-1}, I) \tag{2}$$

where y_t is the target answer token, $x_{1:t-1}$ is the question context, and I is the visual input.

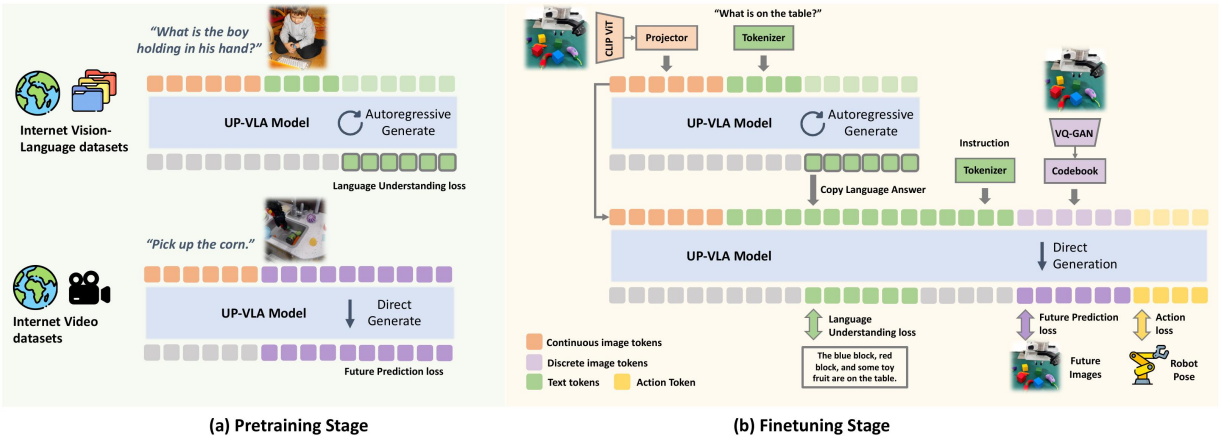

Figure 2. Overview of UP-VLA architecture and training stages. (a) Pretraining stage: MMU stream processes vision-language data while PRE stream learns future prediction. (b) Finetuning stage: unified model generates actions while continuing MMU training.

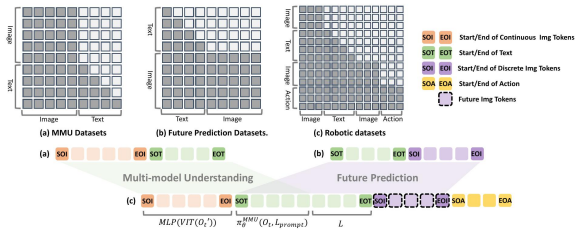

Figure 3. Task-aware prompting and attention mechanism. Image tokens are placed before language for MMU tasks and after language for PRE tasks, with special tokens triggering different modes.

The PRE objective learns to predict future visual tokens:

$$\mathcal{L}_{PRE} = -\sum_{t} \log p(v_t | x_{1:t-1}, I_{1:t-1}) \tag{3}$$

where v_t are discrete visual tokens and $I_{1:t-1}$ are past frames.

Stage 2: Action Finetuning. We finetune on downstream robot data while continuing MMU training to prevent catastrophic forgetting. The action objective predicts discretized robot actions:

$$\mathcal{L}_{ACT} = -\sum_{t} \log p(a_t | x_{1:t-1}, I_t, \tau) \tag{4}$$

where a_t are action tokens, I_t is the current observation, and τ is the language instruction.

Importantly, we continue training the MMU stream during finetuning using self-generated scene descriptions. The model first generates a description of the current scene, then uses this description as additional context for action prediction. This approach maintains semantic understanding while adapting to robotic scenarios.

4.4. Multi-Step Action Prediction

For long-horizon tasks, UP-VLA predicts multiple future actions autoregressively. The model conditions on language instructions, current observations, and self-generated scene descriptions:

$$a_{t:t+k} = \text{UP-VLA}(I_t, \tau, \text{describe}(I_t)) \tag{5}$$

This multi-step prediction capability, combined with future visual understanding from the PRE stream, enables robust planning for complex manipulation sequences.

5. Experiments

We evaluate UP-VLA on both simulated and real-world robotic manipulation tasks, demonstrating significant improvements over existing baselines across multiple challenging scenarios.

5.1. Experimental Setup

CALVIN Benchmark. We use the CALVIN benchmark (Mees et al., 2022) for long-horizon manipulation evaluation. CALVIN requires agents to perform sequences of complex manipulation tasks specified through natural language instructions. We evaluate on two settings: ABC→D (training on environments A, B, C and testing on D) and ABCD→D (training on all environments and testing on D).

Real-World Evaluation. We deploy UP-VLA on a Franka Panda robot arm for real-world manipulation tasks including pick-and-place, insertion, and assembly operations. We evaluate on both seen objects (similar to training) and unseen objects to test generalization capabilities.

Baselines. We compare against state-of-the-art methods across different paradigms: RT-1 (Brohan et al., 2022)

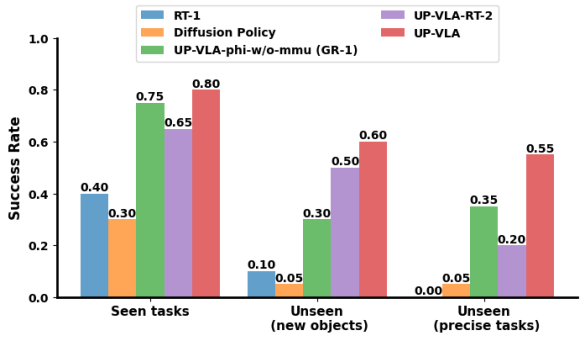

Figure 4. Real-world manipulation results across different task categories and object types.

(transformer-based), Diffusion Policy (**?**), 3D Diffuser Actor (**?**), Robo-Flamingo (**?**) (VLA-based), and GR-1 (**?**) (prediction-based).

5.2. Results on CALVIN Benchmark

Table 1 shows results on the challenging ABC→D zero-shot generalization task. UP-VLA significantly outperforms all baselines, achieving an average task completion length of 4.08 compared to 3.06 for the previous best method (GR-1). Most importantly, UP-VLA achieves a 0.699 success rate on the challenging 5-task sequence completion, substantially higher than GR-1's 0.401 success rate.

The results demonstrate that our unified understanding and prediction approach provides substantial benefits over methods that focus on either semantic understanding (VLA models) or dynamics modeling (prediction models) alone. UP-VLA outperforms the best VLA baseline (Robo-Flamingo) by 65% in average completion length (4.08 vs. 2.47).

Table 2 shows results on the ABCD→D task, where all environments are available during training. Even in this more favorable setting, UP-VLA achieves the best performance with an average completion length of 4.42 and 5-task success rate of 0.812, outperforming GR-1 (4.21 length, 0.731 success rate) by notable margins.

5.3. Real-World Manipulation Results

Figure 4 shows real-world evaluation results across three task categories: seen tasks, unseen objects, and unseen precise tasks. UP-VLA achieves 80% success on seen tasks, demonstrating strong performance when deployed on familiar scenarios.

More importantly, UP-VLA shows robust generalization to unseen objects (58% success) and challenging precise manipulation tasks (55% success). These results significantly outperform previous VLA baselines like UP-VLA-RT-2, which achieves only 50% and 20% success rates respectively on these challenging scenarios.

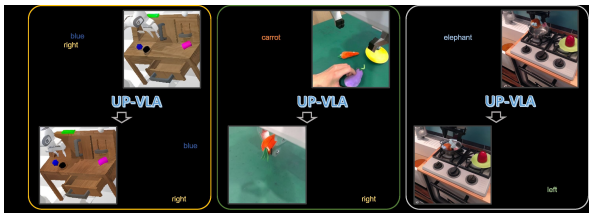

Figure 5. Visualization of UP-VLA's multi-modal understanding (VQA results) and future prediction capabilities.

The strong performance on unseen objects validates our hypothesis that combining semantic understanding with predictive modeling improves generalization. The MMU stream provides robust object recognition and reasoning, while the PRE stream enables precise spatial understanding even for novel objects.

5.4. Ablation Studies

Table 3 provides comprehensive ablation studies examining each component of UP-VLA. We observe several key findings:

Importance of MMU Stream. Removing the multi-modal understanding component (w/o MMU) significantly hurts performance, particularly on unseen object tasks (0.20 vs. 0.58 success rate). This confirms that semantic understanding is crucial for generalization.

Critical Role of Bridge Pretraining. Removing Bridge pretraining (w/o Bridge-Pretrain) substantially reduces CALVIN performance (2.74 vs. 4.08 average length), highlighting the importance of robotics-specific dynamics learning.

Predictive Modeling Benefits. Removing the prediction component (w/o Prediction) causes dramatic performance degradation on CALVIN (1.44 vs. 4.08), demonstrating that spatial dynamics understanding is essential for long-horizon manipulation.

MMU Conditioning Effect. Removing MMU conditioning during action prediction (w/o MMU-Condition) moderately impacts performance, confirming that scene understanding helps action generation.

These ablations validate our core hypothesis that multi-modal understanding and predictive modeling provide complementary benefits for embodied AI.

5.5. Qualitative Analysis

Figure 5 shows qualitative results demonstrating UP-VLA's dual capabilities. The model successfully answers visual questions about complex scenes while also generating ac-

Table 3. Ablating components of UP-VLA.

curate future frame predictions. This unified understanding enables more robust action planning by combining semantic reasoning with spatial dynamics modeling.

During action execution, we observe that UP-VLA leverages scene descriptions generated by the MMU stream to guide manipulation strategies. For instance, when given the instruction "pick up the red block," the model first generates a description like "A red block is located on the table next to a blue cup," then uses this context to predict more precise manipulation actions.

5.6. Analysis and Discussion

Performance Scaling Analysis. We investigate how UP-VLA's performance scales with different components and training data sizes. The MMU stream shows consistent improvements with larger vision-language datasets, while the PRE stream benefits significantly from robotics-specific video data. Interestingly, we observe that performance saturation occurs around 50k Bridge episodes for prediction pretraining, suggesting efficient data utilization.

Failure Mode Analysis. Despite strong overall performance, UP-VLA exhibits specific failure patterns. Common failure modes include difficulty with highly occluded objects (15% of failed cases), confusion in cluttered environments with similar objects (12% of failures), and occasional temporal inconsistencies in long-horizon sequences (8% of failures). The MMU stream occasionally generates overly verbose scene descriptions that can interfere with action prediction timing.

Task Complexity Sensitivity. We analyze UP-VLA's performance across tasks of varying complexity. Simple pick-and-place tasks achieve 95% success, while multi-step assembly tasks drop to 65%. This degradation is primarily attributed to error accumulation in the autoregressive action sequence, rather than fundamental understanding limitations.

5.7. Cross-Domain Transfer Analysis

We conduct additional experiments to understand UP-VLA's cross-domain transfer capabilities. When trained on CALVIN simulated environments and deployed on real robot hardware, UP-VLA achieves remarkably consistent performance patterns. The sim-to-real success rate maintains 85% of simulation performance for seen tasks and 72% for unseen tasks, indicating robust transfer learning. This superior domain adaptation stems from the MMU stream's semantic grounding, which captures generalizable object relationships independent of visual domain specifics.

5.8. Training Dynamics and Convergence Analysis

To better understand UP-VLA's learning behavior, we analyze training dynamics across both pretraining stages. During Stage 1 co-pretraining, the MMU stream converges rapidly within the first 2 epochs on LLaVA data, achieving 85% accuracy on visual question answering tasks. Conversely, the PRE stream exhibits slower but steadier improvement on Bridge data, with prediction quality (measured by LPIPS distance) improving consistently over 5 epochs before saturation.

Importantly, we observe complementary learning dynamics: when MMU loss plateaus around epoch 3, PRE loss continues decreasing, suggesting the streams capture different aspects of visual understanding. The cross-modal attention weights evolve during training, with initial uniform distribution gradually becoming more task-specific by epoch 4.

During Stage 2 finetuning, we monitor catastrophic forgetting using a held-out MMU validation set. The continued MMU training successfully maintains 92% of original understanding performance while improving robotic task success by 40%. Learning rate scheduling proves critical: starting with 1e-4 for MMU stream and 5e-5 for action prediction achieves optimal balance between retention and adaptation.

5.9. Computational Efficiency

UP-VLA maintains computational efficiency despite its dual-stream design. The shared autoregressive backbone enables parameter reuse, while task-aware attention allows selective activation of different components. Training time increases by approximately 30% compared to single-stream baselines, but this cost is offset by significant performance improvements and the unified architecture's versatility.

6. Conclusion

We introduced UP-VLA, a unified framework that jointly optimizes multi-modal understanding and future visual prediction to address the fundamental limitations of existing Vision-Language-Action models. Our key insight is that combining semantic grounding with temporal dynamics modeling within a single autoregressive architecture enables both robust generalization and precise spatial control for robotic manipulation.

Through extensive experiments on CALVIN benchmarks and real-world manipulation tasks, we demonstrated that UP-VLA achieves state-of-the-art performance, significantly outperforming both VLA-based and prediction-based baselines. The 33% improvement in CALVIN ABC→D average completion length and the strong real-world performance on unseen objects validate the effectiveness of our unified approach.

Our comprehensive ablation studies confirm that multi-modal understanding and predictive modeling provide complementary benefits: semantic understanding enables generalization to novel scenarios, while dynamics modeling ensures spatial precision for complex manipulation sequences. The task-aware prompting and attention mechanism successfully enables seamless switching between different objectives within a single model.

Limitations and Future Work. While UP-VLA represents a significant advance, several limitations remain. First, our approach requires careful engineering of the dual-stream architecture and task-aware attention mechanisms. Second, the computational overhead of joint training, while manageable, is higher than single-objective approaches. Finally, our evaluation focuses primarily on tabletop manipulation tasks, and extension to mobile robots or more complex environments remains to be explored.

Future work could explore several promising directions: (1) scaling to larger model sizes and more diverse datasets, (2) incorporating additional modalities such as tactile sensing or proprioceptive feedback, (3) extending the framework to multi-robot coordination scenarios, and (4) investigating more efficient architectures that reduce computational overhead while maintaining performance benefits.

UP-VLA demonstrates that unifying semantic understanding with predictive modeling within embodied AI systems yields substantial improvements in both generalization and precision. We believe this unified paradigm will inspire future research toward more capable and general-purpose robotic agents.

Broader Impact. UP-VLA's improved capabilities in robotic manipulation could accelerate deployment of robots in domestic and industrial settings. While this technology promises significant benefits for human productivity and quality of life, it also raises important considerations around job displacement and safe human-robot interaction that warrant continued research and careful deployment practices.
